**Magnesia
carbon**

Pipe ID:1-3mm

	MHP18	MHP24	MHP32	MHP40	MHP60	MHP100
Pipe Number	18	24	32	40	60	100
Ideal flow NI/min	600	800	1000	1200	1700	2500

Brick design(MHP)

A bottom purging element is not just another piece of magnesia carbon brick that you build slits into and watch it delivering the gas!

Inadequately developed element results in:

Severe thermomechanical stress

Excessive wear and/blockage of slits at a very early stage of converter campaign

Metallurgical benefits achievable only for a meagre part of the campaign.

Temperature distribution in bottom during blowing

Without bottom-blowing, the measurements of bottom show regular fluctuations of the temperature during the cycle(empty-filling-blowing-tapping-empty).

The temperature starts growing at the beginning of filling.

After tapping the lining cools down.

Temperature distribution in bottom during blowing

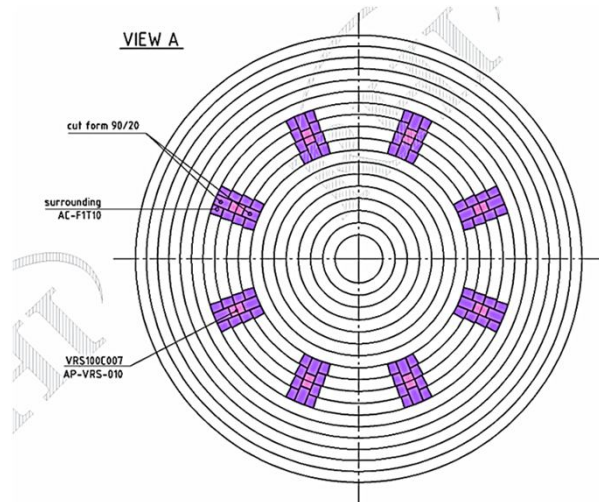

During bottom blowing, the inert gas cools down the lining around an active bottom blowing element (**cold spot**) and the cooling effect is proportional to the flow rate.

Hot face temperature around purge element is in "stiff" range than rest of the bottom.....

Temperature distribution in bottom during blowing

During bottom blowing, the inert gas cools down the lining around an active bottom blowing element (**cold spot**) and the cooling effect is proportional to the flow rate.

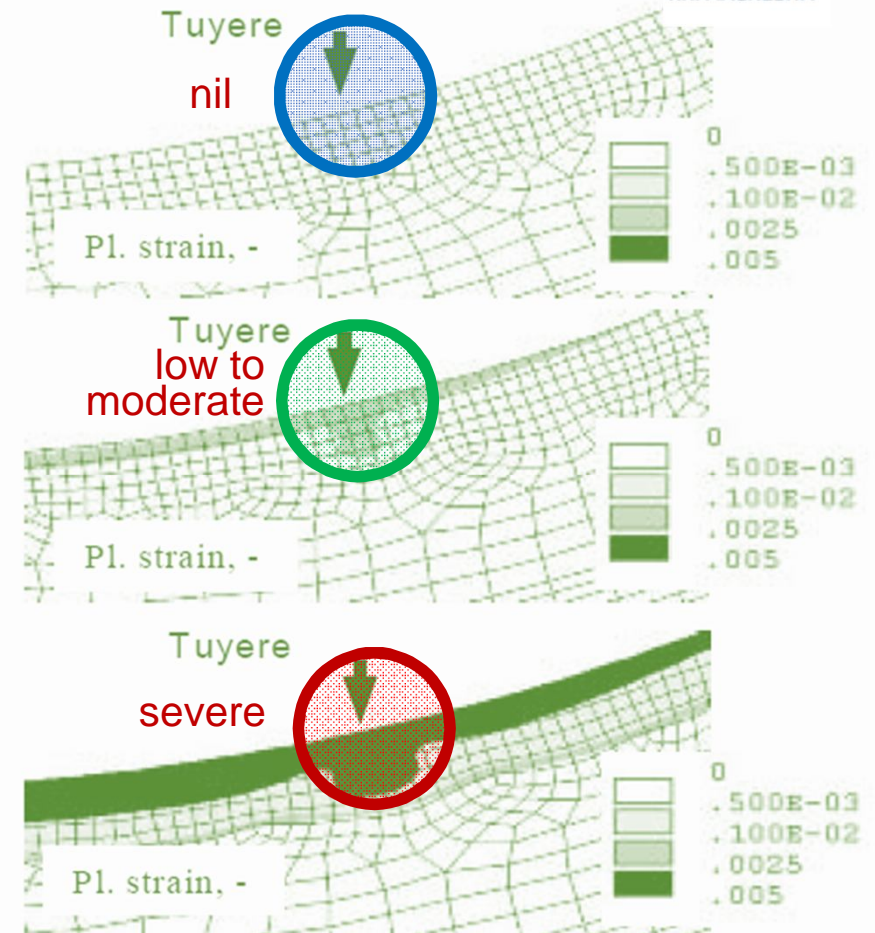

.....so compressive stress here is much higher than rest of the bottom

Plastic strains (compressive damage) during blowing

Compressive stress often high enough to exceed material strength

Makes the blowing element and bricks surrounding it, most vulnerable to compressive spalling.

MgO-C purge plug manufacturers are often tempted to use a refractory that is as strong as possible so that the material can withstand the stress due to cyclic loading.

Well, this holds good so long as the system remains free of cracks!

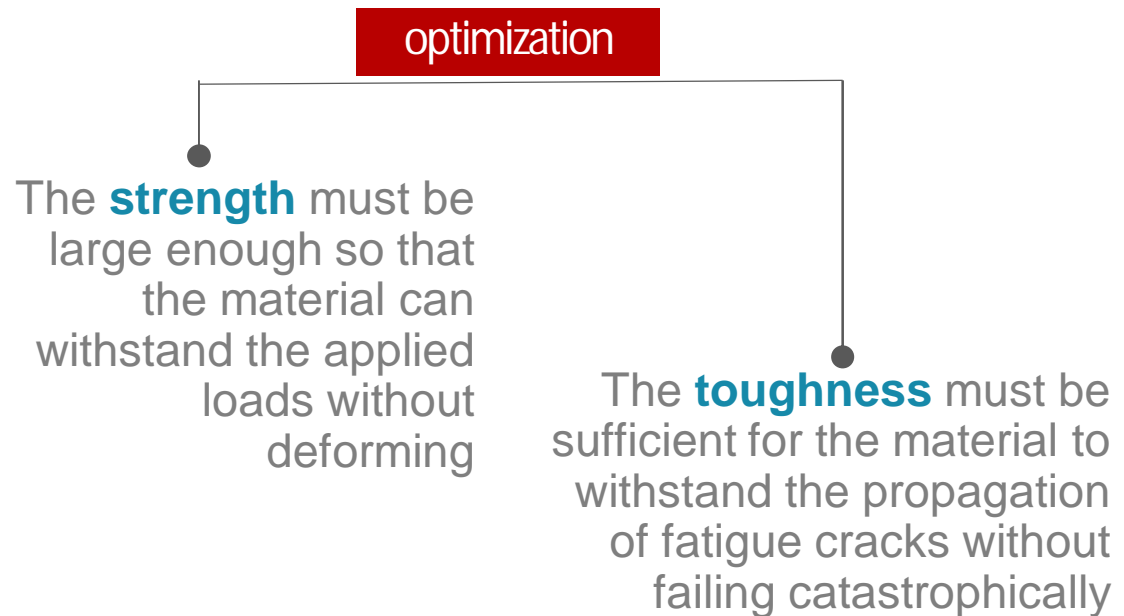

But cracks in MgO-C refractories exposed to fatigue conditions are inevitable!!

In these situations, knowledge of the fracture toughness is required to determine how long the brick can remain in service before the crack grows so long that the intact cross-section cannot support the load, and the brick fractures.

Difference between strength and fracture toughness

Designers must be concerned with both the strength and the toughness of the material being produced

For a given load, as fracture toughness increases, the refractory can tolerate a longer crack before fracturing!

Difference between strength and fracture toughness

Resistance to initiation of crack is important but more important is how ably you can control the crack propagation once it is generated!

This is where the right formulation of the matrix comes into play

quality of magnesia aggregate and graphite flakes used

grain size distribution

aggregate-matrix interface

porosity

right additives and binder

Difference between strength and fracture toughness

Effective tortuousness of crack path

Only a full proof matrix can promote an effective tortuousness of crack path that transforms crack **“activation energy”** and energy dissipation, from **“burst type”** to **“slow releasing type”**.

Two important parameters for selecting the right kind of formulation for bottom purging elements

$$R = \sigma(1 - \nu) / \alpha E$$

- indicative of resistance to **crack initiation** by thermal shock
- represents the maximum temperature gradient before cracks are formed.

That is, the higher the value of R , the greater the resistance to nucleate cracks due to stress by thermal origin

σ_T is the thermal stress
 E is the Young's modulus
 α is the coefficient of linear thermal expansion
 ν is the Poisson's ratio

the parameter R''' is more relevant in refractories since these materials often contain a large population of inherent flaws (pores and microcracks)

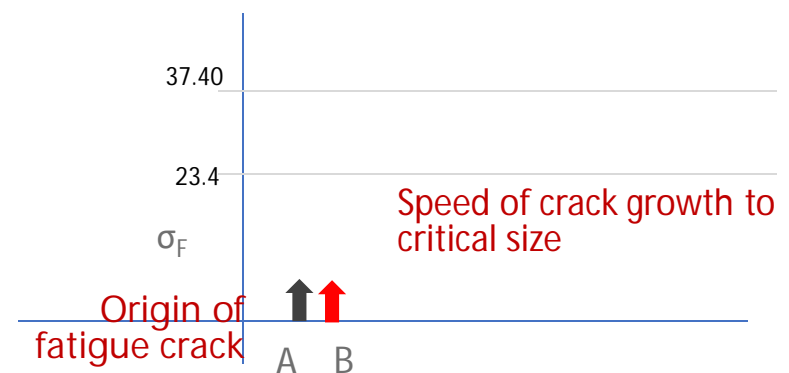

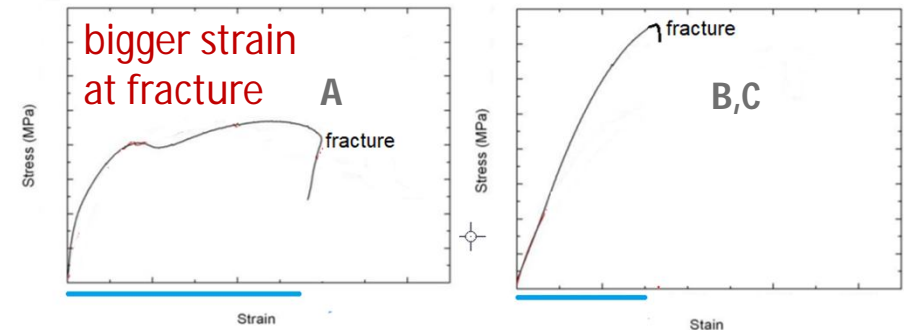

$$R''' = E / \sigma^2 (1 - \nu)$$

- Indicative of resistance to **crack propagation**
- indicates the minimum elastic energy, in the fracture zone, available for the crack propagation

That is, the higher the value of R''' , the greater the resistance to propagation of cracks

BRICK	σ_F (MPa)	ε_F (%)	R(°C)	$R'''(\times 10^{-5} \text{ Pa}^{-1})$
A	23.40	0.50	171	2.90
B	37.40	0.31	327	0.80
C	24.10	0.34	330	1.10

- The brick "A" meets the best combination of parameters R and R'''
- Despite having a lower value of **fracture strength(23.4MPa)**, "A" has a higher value of **deformation % at fracture(0.5%)** owing to a much better placed R''' , thus increasing the strain at fracture.
- For "B" and "C", the higher values of fracture strength is **offset by a speedier propagation of a fatigue crack** to the point of fracture (lesser values of R''')

Factors needed to be addressed

Material properties

The most important parameter is the material flexibility and strength
The right balance of the two!

Bottom structure

Use of different qualities around bottom blowing elements and rest of bottom

Optimization of bottom blowing process

Reduce the cooling effect of the blown gas (optimizing flow rate, channel size)

Pressure, Flow, Velocity: Determining which variable is Important

Understanding the interdependent nature of **pressure, flow and velocity** is important when designing a system but more important is understanding when each variable is the critical design parameter.

Velocity

The force of a fluid comes from the fluid impacting at high velocity. The velocity is increased by forcing a volume of fluid through a constricted outlet. While the fluid is moving very quickly, it is not necessarily a high volumetric flow rate; this is a common misconception.

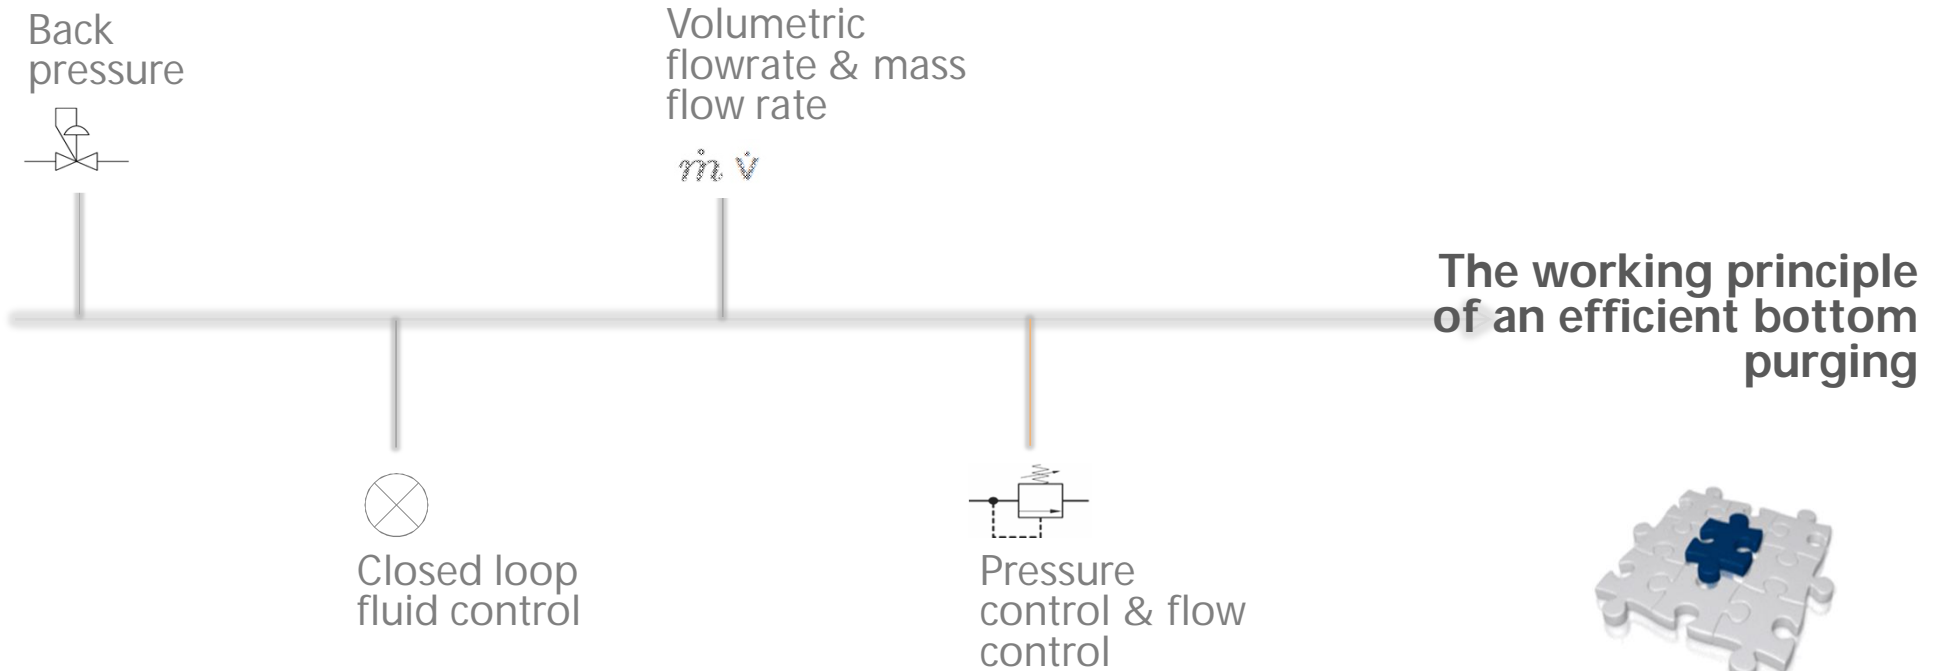

Flow

Flow is critical when the fluid needs to fill a space. You need to supply a given volumetric flow rate that continuously fills and replenishes the application space.

Pressure

If an application is expected to have a high back pressure, the system must be rated to operate at that pressure. Characteristics of a system with a high level of back pressure include multiple lengths or long lengths of hose or pipe and applications where gas is forced through small openings.

Concepts that go into making an efficient bottom purging

The concept of backpressure

When a fluidic substance moves through a pipe, it builds up a lot of kinetic energy and inertia. When that energy hits a wall (say a blockade by infiltrate in the plug), it bounces back like ripples.

How a backpressure works?

The flow remains essentially in the same direction, but the flow is reduced due to resistance.

Open-Loop vs. Closed-Loop Fluid Control

In the simplest terms, if the controller supplies **input** (action) via **feedback from the process itself** and this input is directly related to the **output response** or result, the system is closed-loop, if not it is considered open-loop.

An efficient CIP always thrives on a closed loop control

For obvious reasons, open-loop systems are less accurate, less repeatable and (generally) less costly.

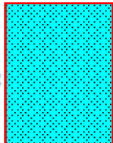

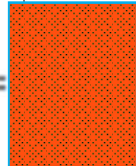

Volumetric flow rate

Volumetric Flow Rate, also called the actual flow rate, is dependent on Pressure & Temperature and hence are recommended for measuring volumetric flow when high accuracy is not needed

Mass flow rate

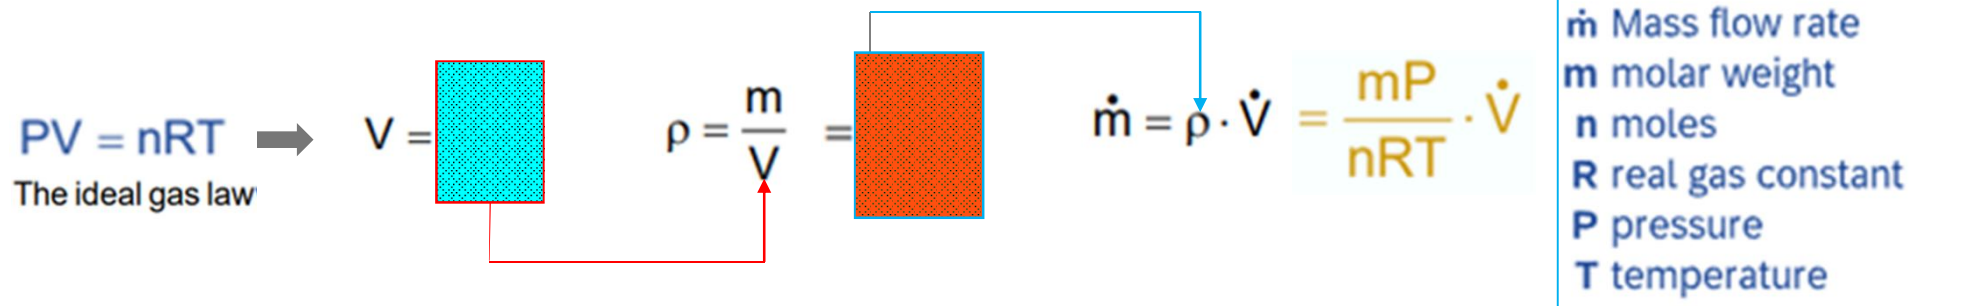

Mass Flow Rate is independent of Pressure & Temperature and hence more reliable with higher accuracy and repeatability.

Relation between Mass flow rate & Volumetric flow rate

$PV = nRT$ → $V =$  $\rho = \frac{m}{V}$ =  $\dot{m} = \rho \cdot \dot{V} = \frac{mP}{nRT} \cdot \dot{V}$

The ideal gas law

\dot{V} Volumetric flowrate
 \dot{m} Mass flow rate
 m molar weight
 n moles
 R real gas constant
 P pressure
 T temperature

Example: a 200 sccm flow sensor with a mass flow rate of 0.250 g/min (200 sccm) for N₂

\dot{m} 0.250 g/min
 m 28 g
 n 1 mole
 R 82.1 (cm³*atm)/(mole*K)
STP
 P 1 atm
 T 273.15 °K

$\tilde{V} =$ cm³/min

\dot{m} 0.250 g/min
 m 28 g
 n 1 mole
 R 82.1 (cm³*atm)/(mole*K)
 Non std.conditions (T has changed)
 P 1 atm
 T 298 °K

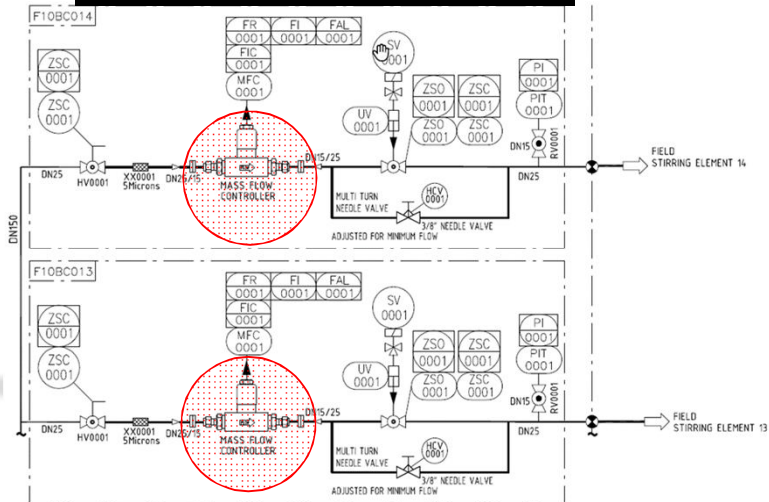

$\tilde{V} =$ 219 cm³/min
 volumetric flow is 219 cm³/min
 mass flow is sccm/min

\dot{m} 0.250 g/min
 m 28 g
 n 1 mole
 R 82.1 (cm³*atm)/(mole*K)
 Non std.conditions (P&T changed)
 P 1.5 atm
 T 298.2 °K

$\tilde{V} =$ 146 cm³/min
 volumetric flow is 146 cm³/min
 mass flow is sccm/min

The mass flow controller will automatically control the flow rate of a gas according to a set flow rate sent as an electric signal, the measured flow being **mass compensated** for any change in temperature and pressure

$$\tilde{V} = \frac{nRT}{mP} \cdot \dot{m}$$

\tilde{V} Volumetric flowrate

\dot{m} Mass flow rate

m molar weight

n moles

R real gas constant

P pressure

T temperature

$$\dot{m} \quad \mathbf{0.250} \text{ g/min}$$

$$m \quad 28 \text{ g}$$

$$n \quad 1 \text{ mole}$$

$$R \quad 82.1 \text{ (cm}^3 \cdot \text{atm)/(mole} \cdot \text{K)}$$

$$P \quad \mathbf{1} \text{ atm}$$

$$T \quad 298.15 \text{ }^\circ\text{K}$$

$$\dot{m} \quad \mathbf{0.250} \text{ g/min}$$

$$m \quad 28 \text{ g}$$

$$n \quad 1 \text{ mole}$$

$$R \quad 82.1 \text{ (cm}^3 \cdot \text{atm)/(mole} \cdot \text{K)}$$

$$P \quad \mathbf{1.5} \text{ atm}$$

$$T \quad 298.15 \text{ }^\circ\text{K}$$

$$\tilde{V} = \mathbf{219} \text{ cm}^3/\text{min}$$

ORIGINAL SCENARIO

$$\tilde{V} = \mathbf{146} \text{ cm}^3/\text{min}$$

CHANGED SCENARIO

Practical problems encountered with a system that works without mass flow controller

Long response time

Systems need a few minutes until the new set values of flow rates are reached (MFCs have a response time <500ms).

This long switchover time increases the risk of blockage.

Inability to ensure precise and stable flow regulation

Particularly at low flow rates; this is especially critical during slag splashing and de-slagging, because minimum gas flow rates are normally applied during these process steps.

Merits of MFC

- Wide regulation ratio 1:50 of MFC(i.e., from 24NI/min to 1200NI/min or from 32NI/min to 1600NI/min).
- Fast step response of the MFC(5-95% in less than 1 second).
- High accuracy of MFC @ +/-1.5%

```
>> done(function(response) {  
  for (var i = 0; i < response.length; i++) {  
    var layer = L.marker(  
      [response[i].latitude, response[i].longitude],  
      {  
        title: response[i].species,  
        alt: response[i].description,  
        popup: L.popup(  
          {maxZoom: 18},  
          {content: response[i].sighted_at} + "  
      }  
    );  
    layer.addTo(map);  
  }  
});  
$.ajax({  
  url: "/api/locations",  
  success: function(response) {  
    done(function(response) {  
      for (var i = 0; i < response.length; i++) {  
        var layer = L.marker(  
          [response[i].latitude, response[i].longitude],  
          {  
            title: response[i].species,  
            alt: response[i].description,  
            popup: L.popup(  
              {maxZoom: 18},  
              {content: response[i].sighted_at} + "  
          }  
        );  
        layer.addTo(map);  
      }  
    });  
  }  
});
```
